## **BEST AVAILABLE IMAGES**

Defective images within this document are accurate representations of the original documents submitted by the applicant.

Defects in the images may include (but are not limited to):

- BLACK BORDERS
- TEXT CUT OFF AT TOP, BOTTOM OR SIDES
- FADED TEXT
- ILLEGIBLE TEXT
- SKEWED/SLANTED IMAGES
- COLORED PHOTOS
- BLACK OR VERY BLACK AND WHITE DARK PHOTOS
- GRAY SCALE DOCUMENTS

**IMAGES ARE BEST AVAILABLE COPY.**

**As rescanning documents *will not* correct images,  
please do not report the images to the  
Image Problem Mailbox.**

## Summary

The presented invention refers to DNA sequences from *Zea mays* (maize), *Solanum tuberosum* (potato) and *Spinacia oleracea* (spinach), which contain the coding region of a glucose-translocator whose introduction into a plant genome changes the development and allocation of carbon molecules in transgenic plants, as well as plasmids, yeasts, bacteria, and transgenic plants, and the introduction of these DNA sequences to change the activity of glucose translocation and the consequent effect on carbon partitioning. Furthermore, the invention affects the use of the described sequences of the glucose-translocators to identify translocators from other plants (angiosperms, gymnosperms, and algae) through hybridization with low stringency or through PCR techniques, as well as the utilization of the glucosetranslocator as a target for herbicides.
